Lab 8
Constructor overloading + Inheritance

1: Create a class Student with data members: name (string), rollNo (int), marks (float). Overload constructors: default constructor initializes with default values "Unknown", 0, 0.0. Parameterized constructor initializes with given values. Display student details using a method.

2: Create a Rectangle class with length and width as data members. Default constructor sets length = width = 1. Parameterized constructor sets custom length and width. Provide a method area() to calculate area. Display area for both types of objects

3: Create an Emloyee class with empId, name, salary. Overload constructors: default sets default values, parameterized sets given values. Use Scanner to input values for parameterized constructor and display both default and user-input employee details.

4:Statement: Create a program where a Vehicle class has a method to display its type, and a Car class inherits from Vehicle to add its specific model name.

5: Create a program where the child class Dog overrides a method sound() from the parent class Animal, but also uses the super keyword to call the parent's version of the method.
